A6.4 Slave ordering

To meet the requirements of the ordering model, a slave must ensure that:

- Any write transaction for which it has issued a response must be observed by any subsequent write or read transaction, regardless of the transaction IDs.
- Any write transaction to Device memory must be observed by any subsequent write to Device memory with the same ID, even if a response has not yet been issued.
- Any write transaction to Normal memory must be observed by any subsequent write to the same or an overlapping address with the same ID, even if a response has not yet been given. This applies, also, to transactions to cacheable memory. That is, it applies to all valid write transactions for which **AWCACHE[3:1]** is not `0b000`.
- Responses to multiple write transactions with the same ID must be issued in the order in which the transactions arrived.
- Responses to multiple write transactions with different IDs can be issued in any order.
- Any read transaction for which it has issued a response must be observed by any subsequent write or read transaction, regardless of the transaction IDs.
- Any read transaction to Device memory must be observed by any subsequent read to Device memory with the same ID, even if a response has not yet been issued.
- Responses to multiple read transactions with the same ID must be issued in the order in which the transactions arrive.
- Responses to multiple read transactions with different IDs can be issued in any order.
